This is the high school interaction data I am using for my second year paper. Specifically, the network I am analyzing here is of the monitored face-to-face interactions. However, because the project is largely focused on comparing the physical interaction data to the diary-log data, I have filtered down the network to only show the nodes who provided the diary data and the individuals they reference in their diary-log. In this network, a tie is registered if the individuals were in face-to-face proximity for at least 20 seconds. The data logged every interaction as a

distinct tie, so I also narrowed down the data to show a maximum of one tie per dyad (I am working on turning the quantity of interactions into a tie weight). As most, but not all (86%) of the students in the school wore the physical sensors, and only 120 (approx. 1/3) provided diary logs, this network is not a perfectly accurate representation of the social space, but it does accurately represent the social space of the individuals of interest for this project.

The network is visualized with nodes sized proportional to their degree centrality, colored based on gender (pink = female, blue = male), and shaped based on if they provided diary-log data (square = yes, circle = no).

There are 3,490 ties present among the 318 nodes, for a density of 0.07, suggesting that while the network looks dense due to the sheer number of interactions, it is relatively quite sparse. The network seems to largely exist in 3 main clusters—one of which seems to have more women than men, another more men than women, and the third a fairly even split between the two. When actually calculating, there are 1,048 F-F interactions, 921 M-M interactions, and 1,412 mixed-gender interactions, suggesting that interactions do not lean strongly homogenous or heterogenous overall (though I suspect the results may be different if we separated them based on the observed sub-groups/communities). Most of the degree centrality seems to be associated with individuals who provided diary-log data—which makes sense here, as the only ties are those involving those individuals. 32% of the ties in the network are between two individuals who both provided diary data, while 68% of dyads who interacted at least once involve someone who did not report their contact diary. The manufactured absence of non-diary to non-diary ties makes triad analysis nonsensical, but the focus of this project is on 1-degree-out ego-nets within the broader structure.
